TEST ASSIGNMENT

Middle Angular Developer

Restaurant Ordering — a real-time web application prototype

01 Context

A restaurant accepts orders through its website. Its menu, prices and item availability change in real time, and the application has to keep up.

02 Your Task

Build a **prototype** that consists of three parts.

SETUP Menu configuration

- Manage categories and items.
- Configure each item's price and availability.
- Mark an item as **open-price**: its price is entered at the moment it is added to an order.
- Any change is reflected in Menu immediately.

MENU Ordering

- Browse a large menu.
- Add items to the cart with a quantity. For open-price items, the user also enters the price.
- Apply a fixed-amount discount to the order.
- Check out. An order must never be placed twice, and the user must be informed of any availability changes before confirming.
- View all orders on a separate page, with each order's status updating in real time.

SERVER Data and real-time updates

- A minimal server that provides the data and real-time updates the frontend needs.
- Any technology works, for example Node.js.

03 General Requirements

Speed

The app opens quickly, runs smoothly on low-end devices and slow connections, stays visually stable while content loads and responds instantly to user input.

Live updates

Menu, price and availability changes appear right away while the user is browsing.

Reliability

Errors are handled gracefully: the user understands what went wrong and can carry on. Neither server errors nor a lost connection break the app.

04 Build Requirements

- The whole project, including the server, installs and runs with one or two commands, as described in the README.
- Build, tests and lint pass. TypeScript runs in strict mode.

05 Tech Stack

Angular · TypeScript · Angular Material / CDK · NgRx or NGXS · Jest, Vitest or Karma

06 Deliverables

A Git repository with a meaningful commit history. Its **README.md** should cover:

- how to run the project;
- your key decisions and the trade-offs behind them;
- what you deliberately simplified;
- what would be needed to make it production-ready.

07 Notes

- This is a prototype, not a production application. We care about your architecture and how you use the tools, not about polish or completeness.
- Anything not specified here is your call. Just explain your choices in the README.

7 days **Submission deadline**
from the day you receive this assignment.
